Manipulating and Formatting the Data in Your Program

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Objectives

After completing this lesson, you should be able to:

- Describe the `String` class and use some of the methods of the `String` class
- Use the JDK documentation to search for and learn how to use a class
- Describe the `StringBuilder` class
- Explain what a constant is and how to use it
- Explain the difference between promoting and casting of variables

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

String Class

```
String hisName = "Fred Smith"; — Standard syntax
```

The new keyword can be used,
but it is not best practice:

```
String herName = new String("Anne Smith");
```

- A `String` object is immutable; its value cannot be changed.
- A `String` object can be used with the string concatenation operator symbol (+) for concatenation.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

- The `String` class is one of the many classes included in the Java class libraries. The `String` class provides you with the ability to store a sequence of characters. You will use the `String` class frequently throughout your programs. Therefore, it is important to understand some of the special characteristics of strings in the Java programming language. Because a `String` object is immutable, its value cannot be changed. (There are technical reasons, beyond the scope of this course, as to why this immutability is useful. One simple example is that this immutability ensures that a `String` can be used by several different classes safely because it cannot be changed.)
- Creating a `String` object using the `new` keyword creates two `String` objects in memory, whereas creating a `String` object by using a string literal creates only one object; therefore, the latter practice is more memory-efficient. To avoid the unnecessary duplication of `String` objects in memory, create `String` objects without using the `new` keyword.

Concatenating Strings

```
String myString = "Hello";
```

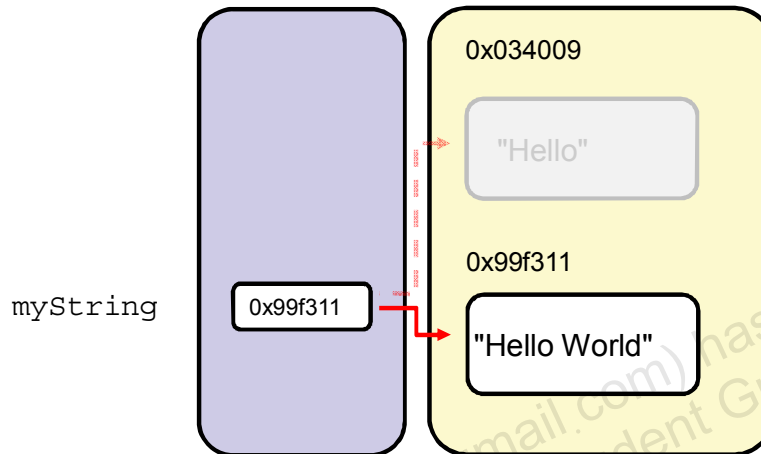

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Because `String` is immutable, concatenating two strings requires creating a new string. The diagram shows a `String` object containing the string "Hello".

Concatenating Strings

```
String myString = "Hello";  
myString = myString.concat(" World");
```

ORACLE

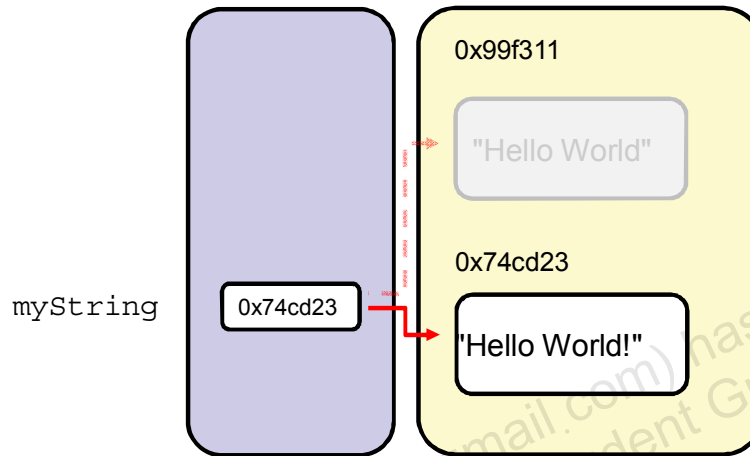

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Here is the string "World" being concatenated to the original string. The `concat` method is being used here, but whether you use that or the concatenation operator (+), a new `String` object is created and a new `String` reference is returned that points to this new object.

In the diagram, this is shown by the fact that the `String` reference `myString` is no longer `0x034009`, and because that object is no longer referred to, it is now inaccessible and will be garbage collected.

Concatenating Strings

```
String myString = "Hello";  
myString = myString.concat(" World");  
myString = myString + "!"
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Finally, on concatenating another string, this time using the concatenation operator, the same thing happens again. A new object is created and the reference for this object is assigned to `myString`.

String Method Calls with Primitive Return Values

A method call can return a single value of any type.

- An example of a method of primitive type `int`:

```
String hello = "Hello World";  
int stringLength = hello.length();
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Like most classes, the `String` class has a number of useful methods. Almost all of these methods do their useful work by returning a single value (Java allows only a single return from a method). The return type (essentially the type of the method) can be a primitive or a reference to an object.

To be able to use the return value in your code, you will typically use the assignment operator to assign the value (or reference) to a type that you have declared for this purpose.

The example in the slide shows the use of reference `hello` to call the method `length`. Because the object this reference refers to is the string `Hello World`, this method call will return the value `11` and place it in the variable `stringLength`. `int` is the type of the method `length`.

String Method Calls with Object Return Values

Method calls returning objects:

```
String greet = " HOW ".trim();  
String lc = greet + "DY".toLowerCase();
```

Or

```
String lc = (greet + "DY").toLowerCase();
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

This example shows several method calls that return object references.

First, the `String` object " HOW " is instantiated and has the method `trim` called on it. Because a string literal returns an object reference, this is exactly the same as calling the method `trim` on the reference. Notice that the string " HOW " has two spaces on either side of the word. The string returned will be just three characters long because these spaces will be removed. This new string will be referenced by `greet`.

The next example shows a method call not being assigned to a type, but simply used in an expression. The method `toLowerCase` is called on the string "DY", returning "dy". `lc` now references an object containing "HOWdy".

Finally, note how an alternative version with parentheses ensures that the two strings are concatenated (creating a new string) before `toLowerCase` is called. `lc` now references an object containing "howdy".

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

Java API Documentation

Consists of a set of webpages;

- Lists all the classes in the API
 - Descriptions of what the class does
 - List of constructors, methods, and fields for the class
- Highly hyperlinked to show the interconnections between classes and to facilitate lookup
- Available on the Oracle website at:
<http://download.oracle.com/javase/8/docs/api/index.html>

ORACLE

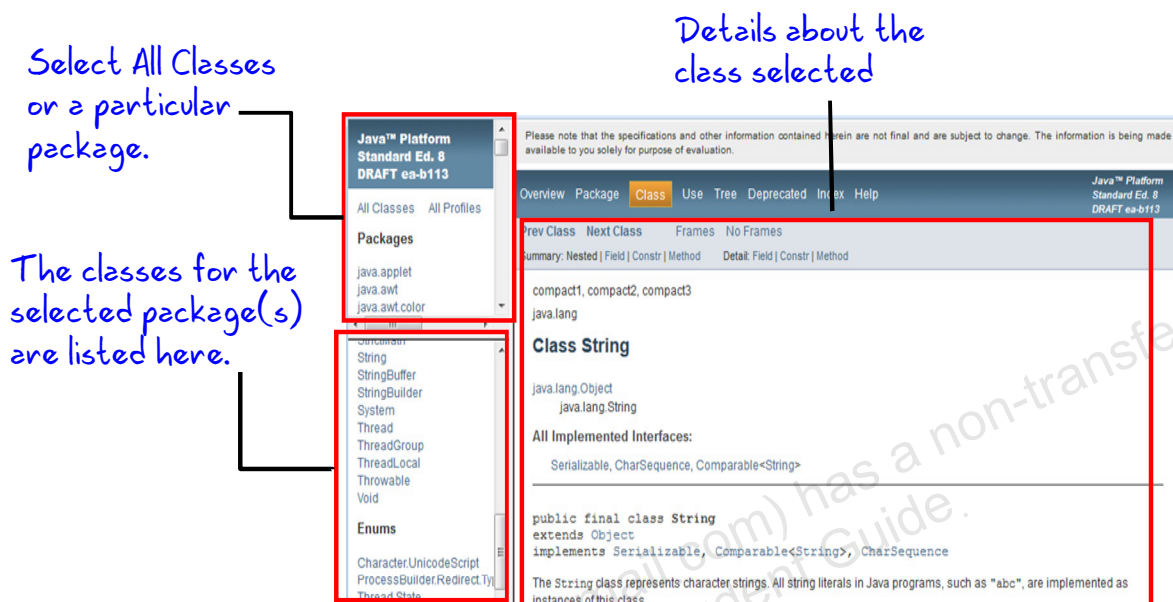

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

All of the Java technology JDKs contain a series of prewritten classes for you to use in your programs. These Java technology class libraries are documented in the Java API documentation for the version of the JDK that you are using. The class library specification is a series of HTML webpages that you can load in your web browser.

A Java class library specification is a very detailed document outlining the classes in the API. Every API includes documentation describing the use of classes and their fields and methods. When you are looking for a way to perform a certain set of tasks, this documentation is the best source for information about the classes in the Java class libraries.

You learn more about constructors in the “Using Encapsulation” lesson.

Java Platform SE 8 Documentation

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

In the screenshot in the slide, you can see the three main panels of the webpage.

The top-right panel allows you to select a package. Java classes are organized into packages, but if you do not know the package of a particular class, you can select All Classes.

The bottom-left panel gives the list of classes in a package, or all classes if that has been selected. In this panel, the class `String` has been selected, populating the main panel on the right with the details of the class `String`. The main panel on the right contains a lot of information about the class, so you need to scroll down to access the information you need.

Java Platform SE 8: Method Summary

```
public int charAt(String str)
```

The return type
of the method

The name of
the method

The type of the parameter that must
be passed into the method

Method Summary	
Methods	
Modifier and Type	Method and Description
char	charAt(int index) Returns the char value at the specified index.
int	codePointAt(int index) Returns the character (Unicode code point) at the specified index.
int	codePointBefore(int index) Returns the character (Unicode code point) before the specified index.
int	codePointCount(int beginIndex, int endIndex) Returns the number of Unicode code points in the specified text range of this String.
int	compareTo(String anotherString) Compares two strings lexicographically.
int	compareToIgnoreCase(String str) Compares two strings lexicographically, ignoring case differences.
String	concat(String str) Concatenates the specified string to the end of this string.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

If you keep scrolling through the details for the `String` class, you will come to the list of methods (only a small subset of this list is shown here).

This master list of methods gives the basic details for the method. In this case, you can see that the name of the method is `charAt`, its type is `char`, and it requires an index (of type `int`) to be passed in. There is also a brief description that this method returns the `char` value at a particular index in the string. For any of the methods, the method name and the parameter types are hyperlinked so that you can get more details.

Java Platform SE 8: Method Detail

Click here to get the detailed description of the method.

int	indexOf(String str)	Returns the index within this string of the first occurrence of the specified substring.
int	indexOf(String str, int fromIndex)	Returns the index within this string of the first occurrence of the specified substring, starting at the specified index.

Detailed description for the `indexOf()` method

Further details about parameters and return value are shown in the method list.

indexOf
<pre>public int indexOf(String str)</pre>
Returns the index within this string of the first occurrence of the specified substring.
The returned index is the smallest value <i>k</i> for which:
<pre> this.startsWith(str, k)</pre>
If no such value of <i>k</i> exists, then -1 is returned.
Parameters:
str - the substring to search for.
Returns:
the index of the first occurrence of the specified substring, or -1 if there is no such occurrence.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

For any of the methods, the method name and the parameter types are hyperlinked so that you can get more details. The example here shows the detailed description for one of the `indexOf()` methods of `String`.

indexOf Method Example

```
1 String phoneNum = "404-543-2345";
2 int idx1 = phoneNum.indexOf('-');
3 System.out.println("index of first dash: " + idx1);
4
5
6 int idx2 = phoneNum.indexOf('-', idx1+1);
7 System.out.println("second dash idx: " + idx2);
```

The 1-arg version

The 2-arg version

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

This example shows how to get the location of the first '-' character by using the 1-arg version of `indexOf`, and then by using the 2-arg version to get the location of the second '-'.

If you wanted to convert the phone number to an `int`, you could do something like this:

1. Find the dashes by using the `indexOf` method (as shown above).
2. Build a new `String` without dashes by using the `substring` method and concatenation.
3. Convert this `String` to an `int` by using the `parseInt` method of `Integer`.

The `parseInt` method of the `Integer` class is covered in the lesson "Using Encapsulation."

Topics

- Using the `String` class
- Using the Java API docs
- **Using the `StringBuilder` class**
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

StringBuilder Class

`StringBuilder` provides a mutable alternative to `String`.

`StringBuilder`:

- Is instantiated using the `new` keyword
- Has many methods for manipulating its value
- Provides better performance because it is mutable
- Can be created with an initial capacity

`String` is still needed because:

- It may be safer to use an immutable object
- A method in the API may require a string
- It has many more methods not available on `StringBuilder`

ORACLE

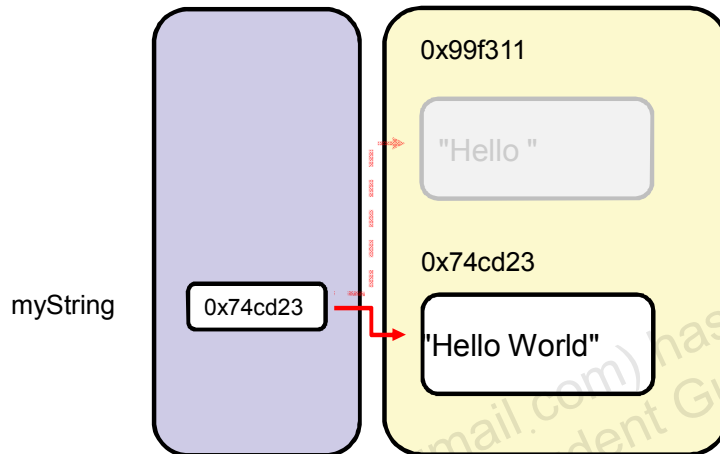

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

The `StringBuilder` class is “mutable.” This means that it can be changed in place. You will recall that when you modify the value of a `String` variable, a new `String` object is created for the new value. `String` objects are “immutable.” A `String` object’s value cannot be changed.

- Unlike `String`, there is no shortcut to instantiate a `StringBuilder`. It is simply instantiated like any other object by using the `new` keyword.
- A small sampling of the `StringBuilder` methods for manipulation of data values are: `append`, `delete`, `insert`, and `replace`.
- `StringBuilder` provides better performance because it does not create new objects in memory whenever a change is made. Performance is also benefited whenever you can set an initial capacity for the object, as opposed to letting it grow and allocate memory dynamically.
- `StringBuilder` is not a complete replacement for `String`, but it is more suitable if many modifications are likely to be made to its value.

StringBuilder Advantages over String for Concatenation (or Appending)

```
String myString = "Hello";  
myString = myString + " World";
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

This slide offers a reminder of what happens when the strings "Hello" and " World" are concatenated. A new `String` object is created, and the reference for that object is assigned to `myString`.

StringBuilder: Declare and Instantiate

```
StringBuilder mySB = new StringBuilder("Hello");
```

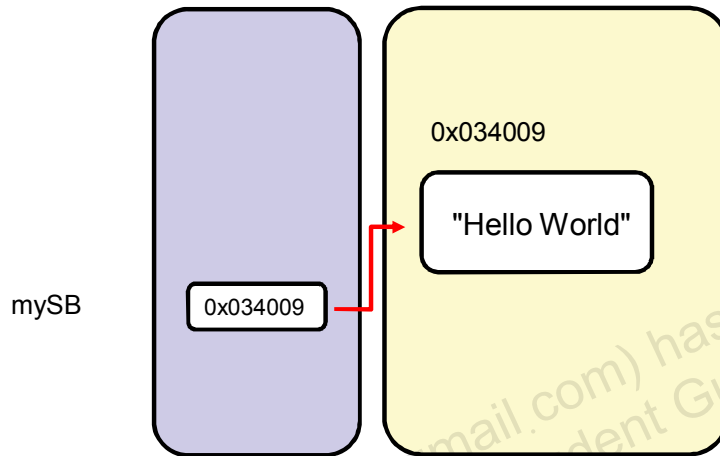

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

This diagram shows the start of a sequence involving a `StringBuilder`. A new `StringBuilder` is instantiated, populated with the string `"Hello"`, and the reference for this new object is assigned to `mySB`.

StringBuilder Append

```
StringBuilder mySB = new StringBuilder("Hello");  
mySB.append(" World");
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

To append the string " World", all you need to do is call the `append` method and pass in "World". Note that no assignment (`=`) is necessary because there is already a reference to the `StringBuilder` object, and this `StringBuilder` object now contains a representation of the combined strings "Hello World".

Even if you did assign the return type of the `append` method (which is `StringBuilder`), there would still be no object creation cost; the `append` method modifies the current object and returns the reference to that object, the one already contained in `mySB`.

Quiz

Which of the following statements are true? (Choose all that apply.)

- a. The dot (.) operator creates a new object instance.
- b. The `String` class provides you with the ability to store a sequence of characters.
- c. The Java API specification contains documentation for all of the classes in a Java technology product.
- d. `String` objects cannot be modified.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Answer: b, c, d

Exercise 7-1: Use `indexOf` and `substring` Methods

In this exercise, you use `indexOf` and `substring` methods to get just the customer's first name and display it.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

- Open the Java Code Console and access 07-ManipulateFormat > Exercise1.
- Follow the instructions below the code editor to:
 - Use the `indexOf` method to get the index of the space character (" ") within `custName`. Assign it to `spaceIdx`.
 - Use the `substring` method and the `spaceIdx` to get just the first name portion of `custName`. Assign it to `firstName`. Print `firstName`.
- If you need help, click the Solution link. To go back to your code, click the Exercise link again. Any changes that you have made will have been saved.

Exercise 7-2: Instantiate the `StringBuilder` object

In this exercise, you instantiate a `StringBuilder` object, initializing it to `firstName` using the `StringBuilder` constructor.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

- Open the Java Code Console and access 07-ManipulateFormat > Exercise2.
- Follow the instructions below the code editor to:
 - Instantiate the `StringBuilder` object (`sb`), initializing it to `firstName`, using the `StringBuilder` constructor.
 - Use the `append` method of the `StringBuilder` object to put the customer full name back together again, and then print the `StringBuilder` object.
- If you need help, click the Solution link. To go back to your code, click the Exercise link again. Any changes that you have made will have been saved.

Topics

- Using the `String` class
- Using the Java API docs

Primitive Data Types

- Integral types (byte, short, int, and long)
- Floating point types (float and double)
- Textual type (char)
- Logical type (boolean)

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Many of the values in Java technology programs are stored as primitive data types. The slide lists the eight primitive types built in to the Java programming language. You have already learned about some of these and have been using them in your exercises and practices. Now you will see the remaining primitive types.

Some New Integral Primitive Types

Type	Length	Range
<code>byte</code>	8 bits	-2^7 to $2^7 - 1$ (-128 to 127, or 256 possible values)
<code>short</code>	16 bits	-2^{15} to $2^{15} - 1$ (-32,768 to 32,767, or 65,535 possible values)
<code>int</code>	32 bits	-2^{31} to $2^{31} - 1$ (-2,147,483,648 to 2,147,483,647, or 4,294,967,296 possible values)
<code>long</code>	64 bits	-2^{63} to $2^{63} - 1$ (-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807, or 18,446,744,073,709,551,616 possible values)

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

There are four integral primitive types in the Java programming language. You have already been using the `int` data type, so the focus here is on the other three. Integral types are used to store numbers that do not have decimal portions. They are shown here in order of size.

- `byte`: If you need to store people's ages, a variable of type `byte` would work because `byte` types can accept values in that range.
- `short`: A `short` will hold 16 bits of data.
- `long`: When you specify a literal value for a `long` type, put a capital `L` to the right of the value to explicitly state that it is a `long` type. Integer literals are assumed by the compiler to be of type `int` unless you specify otherwise by using an `L` indicating `long` type.
- You can express any of the integral types as `binary` (0s and 1s). For instance, a `binary` expression of the number 2 is shown as an allowed value of the `byte` integral type. The binary value is `0b10`. Notice that this value starts with `0b` (that is, zero followed by either a lowercase or uppercase letter `B`). This indicates to the compiler that a `binary` value follows.

Examples of allowed literal values:

- `byte` = 2, -114, 0b10 (binary number)
- `short` = 2, -32699
- `int` (default type for integral literals) = 2, 147334778, 123_456_678
- `long` = 2, -2036854775808L, 1

Note: The only reason to use the `byte` and `short` types in programs is to save memory consumption. Because most modern desktop computers contain an abundance of memory, most desktop application programmers do not use `byte` and `short` types. This course uses primarily `int` and `long` types in the examples.

David Hurtado (davos8900@gmail.com) has a non-transferable license to use this Student Guide.

Floating Point Primitive Types

Type	Float Length
<code>float</code>	32 bits
<code>double</code> (default type for floating point literals)	64 bits

Example:

```
public float pi = 3.141592F;
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

There are two types for floating point numbers: `float` and `double`. Again, the focus is on the new data type here, the `float`. Floating point types are used to store numbers with values to the right of the decimal point, such as 12.24 or 3.14159.

- `float` is used to store smaller floating point numbers. A float variable can hold 32 bits.
- Floating point values are assumed to be of type `double` unless you specify by putting a capital F (`float`) to the right of the value to explicitly state that it is a `float` type, not a `double` type.

Examples of allowed literal values:

```
float = 99F, -327456, 99.01F, 4.2E6F (engineering notation for 4.2 * 106)
```

```
double = -1111, 2.1E12, 99970132745699.999
```

Note: Use the `double` type when a greater range or higher accuracy is needed.

Textual Primitive Type

- The only primitive textual data type is `char`.
- It is used for a single character (16 bits).
- Example:

```
- public char colorCode = 'U';
```

Single quotes must be used with `char` literal values.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Another data type that you use for storing and manipulating data is single-character information. The primitive type used for storing a single character (such as a 'y') is `char`, which is 16 bits in size. The `Shirt` class shows the use of one textual literal value to specify the default value for a `colorCode`:

```
public char colorCode = 'U';
```

When you assign a literal value to a `char` variable, you must use single quotation marks around the character as shown in the code example above.

Java Language Trivia: Unicode

- Unicode is a standard character encoding system.
 - It uses a 16-bit character set.
 - It can store all the necessary characters from most languages.
 - Programs can be written so they display the correct language for most countries.

Character	UTF-16	UTF-8	UCS-2
A	0041	41	0041
c	0063	63	0063
Ö	00F6	C3 B6	00F6
華	4E9C	E4 BA 9C	4E9C
é	D834 DD1E	F0 9D 84 9E	N/A

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Did You Know? Many older computer languages use American Standard Code for Information Interchange (ASCII), an 8-bit character set that has an entry for every English character, punctuation mark, number, and so on.

The Java programming language uses a 16-bit character set called Unicode that can store all the necessary displayable characters from the vast majority of languages used in the modern world. Therefore, your programs can be written so that they work correctly and display the correct language for most countries. Unicode contains a subset of ASCII (the first 128 characters).

Constants

- Variable (can change):
 - `double salesTax = 6.25;`
- Constant (cannot change):
 - `final int NUMBER_OF_MONTHS = 12;`

The `final` keyword causes a variable to be read only.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

In this lesson, you have learned about variables that have values that you can change. In this section, you learn how to use constants to represent values that cannot change.

Assume that you are writing part of a scheduling application, and you need to refer to the number of months in a year. Make the variable a constant by using the `final` keyword to inform the compiler that you do not want the value of the variable to be changed after it has been initialized. Example:

```
final int NUMBER_OF_MONTHS = 12;
```

Any values that do not need to change are good candidates for a constant variable (for example, `MAX_COUNT`, or `PI`).

If someone attempts to change the value of a constant after it has already been assigned a value, the compiler gives an error message. If you modify your code to provide a different value for the constant, you need to recompile your program.

Guidelines for Naming Constants

You should name constants so that they can be easily identified. Generally, constants should be capitalized, with words separated by an underscore (_).

Quiz

The variable declaration `public int myInteger=10;` adheres to the variable declaration and initialization syntax.

- a. True
- b. False

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Answer: a

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- **Using the remaining numeric operators**
- Promoting and casting variables

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Modulus Operator

Purpose	Operator	Example	Comments
Remainder	$\%$ <i>modulus</i>	<pre>num1 = 31; num2 = 6; mod = num1 % num2; mod is 1</pre>	<p>Remainder finds the remainder of the first number divided by the second number.</p> <pre> 5 R 1 6 31 30 --- 1 </pre> <p>Remainder always gives an answer with the same sign as the first operand.</p>

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Programs do a lot of mathematical calculating, from the simple to the complex. Arithmetic operators let you specify how the numerical values within variables should be evaluated or combined. The standard mathematical operators (often called *binary operators*) used in the Java programming language are shown in the tables in this section.

Note: The $\%$ is known as the modulus operator.

Combining Operators to Make Assignments

Purpose	Operator	Examples <code>int a = 6, b = 2;</code>	Result
Add to and assign	<code>+=</code>	<code>a += b</code>	<code>a = 8</code>
Subtract from and assign	<code>-=</code>	<code>a -= b</code>	<code>a = 4</code>
Multiply by and assign	<code>*=</code>	<code>a *= b</code>	<code>a = 12</code>
Divide by and assign	<code>/=</code>	<code>a /= b</code>	<code>a = 3</code>
Get remainder and assign	<code>%=</code>	<code>a %= b</code>	<code>a = 0</code>

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Several very useful shortcuts are shown in the table above. You can combine any operator with the equal sign to abbreviate your code. For example:

```
a = a + b;
```

can be expressed as:

```
a += b;
```

More on Increment and Decrement Operators

Operator	Purpose	Example
++	Preincrement (++ <i>variable</i>)	<pre>int id = 6; int newId = ++id; id is 7, newId is 7</pre>
	Postincrement (<i>variable</i> ++)	<pre>int id = 6; int newId = id++; id is 7, newId is 6</pre>
--	Predecrement (-- <i>variable</i>)	(same principle applies)
	Postdecrement (<i>variable</i> --)	

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

You have used increment and decrement operators before, placing them *after* the variable that you wish to affect. But did you know that these operators can come before (preincrement and predecrement) or after (postincrement and postdecrement) a variable.

When you put the ++ or -- operator before a variable, the value is changed immediately. When you put the operator after the variable, it is not changed until after that expression is evaluated.

- In the first code example above, `id` is initialized to 6. In the next line, you see `newId = ++id`. Because the operator precedes `id`, this increment is immediately evaluated and, therefore, the value assigned to `newId` is 7.
- In the second code example, the ++ operator follows `id`, rather than precedes it. `id` was incremented after the assignment occurred. Therefore, `newId` is 6.
- These same behaviors apply to a decrement (--) operator, in regard to its placement before or after the variable.

Increment and Decrement Operators (++ and --)

Examples:

```
1  int count=15;
2  int a, b, c, d;
3  a = count++;
4  b = count;
5  c = ++count;
6  d = count;
7  System.out.println(a + ", " + b + ", " + c + ", " + d);
```

Output:

15, 16, 17, 17

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

The example in the slide shows basic use of the increment and decrement operators:

```
int count=15;
int a, b, c, d;
a = count++;
b = count;
c = ++count;
d = count;
System.out.println(a + ", " + b + ", " + c + ", " + d);
```

The result of this code fragment is:

15, 16, 17, 17

Discussion: What is the result of the following code?

```
int i = 16;
System.out.println(++i + " " + i++ + " " + i);
```

Topics

- Using the `String` class
- Using the Java API docs
- Using the `StringBuilder` class
- Doing more with primitive data types
- Using the remaining numeric operators
- Promoting and casting variables

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Promotion

- Automatic promotions:
 - If you assign a smaller type to a larger type

- If you assign an integral type to a floating point type

- Examples of automatic promotions:

- `long intToLong = 6;`
 - `double intToDouble = 3;`

ORACLE

In some circumstances, the compiler changes the type of a variable to a type that supports a larger size value. This action is referred to as a *promotion*. Some promotions are done automatically by the compiler. These promotions include:

- If you assign a smaller type (on the right of the =) to a larger type (on the left of the =)
- If you assign an integral type to a floating point type (However, in some cases, such as an assignment of long to float, this could lead to loss of data.)

Caution with Promotion

Equation:

55555 * 66666 = 3703629630

Example of potential issue:

```
1 int num1 = 55555;
2 int num2 = 66666;
3 long num3;
4 num3 = num1 * num2;           //num3 is -591337666
```

Example of potential solution:

```
1 int num1 = 55555;
2 long num2 = 66666;           ——— Changed from int to long
3 long num3;
4 num3 = num1 * num2;           //num3 is 3703629630
```

Before being assigned to a variable, the result of an equation is placed in a temporary location in memory. The location's size is always equal to the size of an `int` type or the size of the largest data type used in the expression or statement. For example, if your equation multiplies two `int` types, the container size will be an `int` type in size, or 32 bits.

If the two values that you multiply yield a value that is beyond the scope of an `int` type, (such as $55555 * 66666 = 3,703,629,630$, which is too big to fit in an `int` type), the `int` value must be truncated to fit the result into the temporary location in memory. This calculation ultimately yields an incorrect answer because the variable for your answer receives a truncated value (regardless of the type used for your answer). To solve this problem, set at least one of the variables in your equation to the `long` type to ensure the largest possible temporary container size.

Caution with Promotion

Equation:

$$7 / 2 = 3.5$$

Example of potential issue:

```
1 int num1 = 7;
2 int num2 = 2;
3 double num3;
4 num3 = num1 / num2;           //num3 is 3.0
```

Example of potential solution:

```
1 int num1 = 7;
2 double num2 = 2; ——— Changed from int to double
3 double num3;
4 num3 = num1 / num2;           //num3 is 3.5
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

The same issue occurs with other data types. Before being assigned to a variable, the result of an equation is placed in a temporary location in memory. The location's size is always equal to the size of the largest data type used in the expression or statement. For example, if your equation divides two `int` types, the container size will be an `int` type in size, or 32 bits. If the two values that you use yield a value that is beyond the scope of an `int` type, (such as $7 / 2 = 3.5$), the value must be truncated to fit the result into the temporary location in memory. This calculation ultimately yields an incorrect answer because the variable for your answer receives a truncated value (regardless of the type used for your answer). To solve this problem, set at least one of the variables in your equation to the `double` type to ensure the largest possible temporary container size.

Type Casting

- When to cast:
 - If you assign a larger type to a smaller type

- If you assign a floating point type to an integral type

- Examples of casting:
 - `int longToInt = (int) 20L;`
 - `short doubleToShort = (short) 3.0;`

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Type casting lowers the range of a value, chopping it down to use a smaller amount of memory, by changing the type of the value (for example, by converting a `long` value to an `int` value). You do this so that you can use methods that accept only certain types as arguments, so that you can assign values to a variable of a smaller data type, or so that you can save memory.

The syntax for type casting a value is: **identifier = (target_type) value**, where:

- `identifier` is the name you assign to the variable
- `value` is the value you want to assign to the identifier
- `(target_type)` is the type to which you want to type cast the value. Notice that the `target_type` must be in parentheses.

Caution with Type Casting

Example of potential issue:

```
1 int myInt;  
2 long myLong = 123987654321L;  
3 myInt = (int) (myLong); // Number is "chopped"  
4                          // myInt is -566397263
```

Safer example of casting:

```
1 int myInt;  
2 long myLong = 99L;  
3 myInt = (int) (myLong); // No data loss, only zeroes.  
4                          // myInt is 99
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

The loss of precision with casting can sometimes lead to situations where numbers are truncated, leading to errors in calculations.

Caution with Type Casting

- Be aware of the possibility of lost precision.

Example of potential issue:

```
1 int myInt;  
2 double myPercent = 51.9;  
3 myInt = (int) (myPercent); // Number is "chopped"  
4                               // myInt is 51
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

If you type cast a float or double value with a fractional part to an integral type such as an int, all decimal values are lost. However, this method of type casting is sometimes useful if you want to truncate the number down to the whole number (for example, 51.9 becomes 51).

Using Promotion and Casting

Example of potential issue:

```
1 int num1 = 53; // 32 bits of memory to hold the value
2 int num2 = 47; // 32 bits of memory to hold the value
3 byte num3;      // 8 bits of memory reserved
4 num3 = (num1 + num2); // causes compiler error
```

Solution using a larger type for num3:

```
1 int num1 = 53;
2 int num2 = 47;
3 int num3; ——— Changed from byte to int
4 num3 = (num1 + num2);
```

Solution using casting:

```
1 int num1 = 53; // 32 bits of memory to hold the value
2 int num2 = 47; // 32 bits of memory to hold the value
3 byte num3;      // 8 bits of memory reserved
4 num3 = (byte) (num1 + num2); // no data loss
```

Assigning a variable or an expression to another variable can lead to a mismatch between the data types of the calculation and the storage location that you are using to save the result. Specifically, the compiler will either recognize that precision will be lost and not allow you to compile the program, or the result will be incorrect. To fix this problem, variable types have to be either promoted to a larger size type, or type cast to a smaller size type. In the above example, the compiler assumes that because you are adding `int` values, the result will overflow the space allocated for a `byte`.

A `byte`, though smaller than an `int`, is large enough to store a value of 100. However, the compiler will not make this assignment and, instead, issues a “possible loss of precision” error because a `byte` value is smaller than an `int` value. To fix this problem, you can either type cast the right-side data type down to match the left-side data type, or declare the variable on the left side (`num3`) to be a larger data type, such as an `int`.

Compiler Assumptions for Integral and Floating Point Data Types

- Most operations result in an `int` or `long`:
 - `byte`, `char`, and `short` values are automatically promoted to `int` prior to an operation.
 - If an expression contains a `long`, the entire expression is promoted to `long`.
- If an expression contains a floating point, the entire expression is promoted to a floating point.
- All literal floating point values are viewed as `double`.

ORACLE

The Java technology compiler makes certain assumptions when it evaluates expressions. You must understand these assumptions to make the appropriate type casts or other accommodations. The next few slides give examples.

Automatic Promotion

Example of potential problem:

```
short a, b, c;  
a = 1 ;  
b = 2 ;  
c = a + b ; //compiler error
```

a and b are automatically promoted to integers.

Example of potential solutions:

- Declare `c` as an `int` type in the original declaration:

```
int c;
```

- Type cast the `(a+b)` result in the assignment line:

```
c = (short) (a+b);
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

In the following example, an error occurs because two of the three operands (`a` and `b`) are automatically promoted from a `short` type to an `int` type before they are added. In the last line, the values of `a` and `b` are converted to `int` types and the converted values are added to give an `int` result. Then the assignment operator (`=`) attempts to assign the `int` result to the `short` variable (`c`). However, this assignment is illegal and causes a compiler error.

The code works if you do either of the following:

- Declare `c` as an `int` in the original declaration:

```
int c;
```
- Type cast the `(a+b)` result in the assignment line:

```
c = (short) (a+b);
```

Using a long

```
1 public class Person {
2
3     public int ageYears = 32;
4
5     public void calculateAge() {
6
7         int ageDays = ageYears * 365;
8         long ageSeconds = ageYears * 365 * 24L * 60 * 60;
9
10        System.out.println("You are " + ageDays + " days old.");
11        System.out.println("You are " + ageSeconds + " seconds old.");
12    } // end of calculateAge method
13 } // end of class
```

Using the L to indicate a long
will result in the compiler
recognizing the total result as
a long.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

The code example uses principles from this section to calculate a person's age in days and seconds. Because the `ageSeconds` variable is declared as a `long`, one of the literal values used as operands in the assigned expression must be initialized as a `long` value ('L') so that the compiler will allow the assignment.

Using Floating Points

Example of potential problem:

Expressions are automatically promoted to floating points.

```
int num1 = 1 + 2 + 3 + 4.0; //compiler error
int num2 = (1 + 2 + 3 + 4) * 1.0; //compiler error
```

Example of potential solutions:

- Declare num1 and num2 as double types:

```
double num1 = 1 + 2 + 3 + 4.0; //10.0
double num2 = (1 + 2 + 3 + 4) * 1.0; //10.0
```

- Type cast num1 and num2 as int types in the assignment line:

```
int num1 = (int) (1 + 2 + 3 + 4.0); //10
int num2 = (int) ((1 + 2 + 3 + 4) * 1.0); //10
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

If an expression contains a floating point, the entire expression is promoted to a floating point.

Floating Point Data Types and Assignment

- Example of potential problem:

```
float float1 = 27.9; //compiler error
```

- Example of potential solutions:

- The `F` notifies the compiler that 27.9 is a `float` value:

```
float float1 = 27.9F;
```

- 27.9 is cast to a `float` type:

```
float float1 = (float) 27.9;
```

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Just as integral types default to `int` under some circumstances, values assigned to floating point types always default to a `double` type, unless you specifically state that the value is a `float` type.

For example, the following line causes a compiler error. Because 27.9 is assumed to be a `double` type, a compiler error occurs because a `double` type value cannot fit into a `float` variable.

```
float float1 = 27.9; //compiler error
```

Both of the following work correctly:

- The `F` notifies the compiler that 27.9 is a `float` value:

```
float float1 = 27.9F;
```

- 27.9 is cast to a `float` type:

```
float float1 = (float) 27.9;
```

Quiz

Which statements are true?

- a. There are eight primitive types built in to the Java programming language.
- b. `byte`, `short`, `char`, and `long` are the four integral primitive data types in the Java programming language.
- c. A boolean type variable holds `true`, `false`, and `nil`.
- d. `short Long = 10;` is a valid statement that adheres to the variable declaration and initialization syntax.

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

Answer: a, d

- a is correct.
- b is incorrect. It should be `byte`, `short`, `int`, and `long`.
- c is incorrect because a boolean type variable holds only `true` and `false`.
- d is correct. `long` is a reserved keyword but `Long` is not.

Exercise 7-3: Declare a Long, Float, and Char

In this exercise, you experiment with the data types introduced in this lesson. You:

- Declare and initialize variables
- Cast one numeric type to another

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

- Open the Java Code Console and access 07-ManipulateFormat > Exercise3.
- Follow the instructions below the code editor to:
 - Declare a `long`, using the `L` to indicate a `long` value. Make it a very large number (in the billions).
 - Declare and initialize a `float` and a `char`.
 - Print the `long` variable with a suitable label.
 - Assign the `long` to the `int` variable. Correct the syntax error by casting the `long` as an `int`.
 - Print the `int` variable. Note the change in value when you run it.
- If you need help, click the Solution link. To go back to your code, click the Exercise link again. Any changes that you have made will have been saved.

Summary

In this lesson, you should have learned how to:

- Describe the `String` class and use some of the methods of the `String` class
- Use the JDK documentation to search for and learn how to use a class
- Use the `StringBuilder` class to manipulate string data
- Create a constant by using the `final` keyword in the variable declaration
- Describe how the Java compiler can use promotion or casting to interpret expressions and avoid a compiler error

Play Time!

Play **Basic Puzzle 8** before the lesson titled “Creating and Using Methods.”

Consider the following:

What happens when you rotate the blue wheel?

How else can you affect the rotation of bumpers?

ORACLE

Copyright © 2014, Oracle and/or its affiliates. All rights reserved.

You will be asked these question in the lesson titled “Creating and Using Methods.”

Practice 7-1 Overview: Manipulating Text

This practice covers the following topics:

- Searching for a particular player and printing out the last name
- Reversing the player name so that the family name is printed first
